Abstract: We describe five new species of *Elaphomyces* from Bartlett Experimental Forest, New Hampshire, USA (*E. americanus*, *E. bartlettii*, *E. macrosporus*, *E. oreoides*, and *E. remickii*) and revise the description of a sixth previously published species (*E. verruculosus*). Of the five new species, *E. bartlettii* and *E. remickii* are only known from New Hampshire whereas *E. americanus*, *E. macrosporus*, and *E. oreoides* are widely distributed in eastern North America. *Elaphomyces verruculosus* is the most widespread and abundant *Elaphomyces* species in eastern North America with a distribution extending from eastern Canada south to northeastern Mexico. All six *Elaphomyces* species are putatively associated with *Tsuga canadensis*, a tree species in regional decline. For five of the six *Elaphomyces* species, we report partially consumed ascocata or rodent fecal samples containing spores, indicating that small mammals play a key role in dispersing these *Elaphomyces* species and that the *Elaphomyces* are an important part of the small mammals' diet.

INTRODUCTION

The truffle genus *Elaphomyces* (Elaphomycetaceae, Eurotiales, Ascomycota) is characterized by a gleba composed of powdery ascospores encased in a thick peridium. The genus is ectomycorrhizal with many vascular plant taxa and occurs in both the Northern and Southern Hemispheres (Castellano *et al.* 2011, 2012a, b, c, 2016, Reynolds 2011, Trappe *et al.* 2009). In northeastern North America, the genus is ecologically important because it forms mycorrhizal associations with a diversity of tree species and comprises a substantial portion of the diets of mycophagous mammals (Vernes *et al.* 2004, Vernes & Poirier 2007). Recent truffle ascocata sampling conducted at Bartlett Experimental Forest, New Hampshire, USA, in stands dominated by eastern hemlock (*Tsuga canadensis*) and American beech (*Fagus grandifolia*) indicates a high diversity of *Elaphomyces* in the Northeast. Using a systematic sampling approach across forest types we sampled 768 4-m² plots, detecting six *Elaphomyces* species. Here we describe five of the *Elaphomyces* species as new, and provide a revised description of a sixth previously published species. Of the five new species, *E. bartlettii* and *E. remickii* are only known from New Hampshire whereas *E. americanus*, *E. macrosporus*, and *E. oreoides* are widely distributed in eastern North America. *Elaphomyces verruculosus* was previously described and is the most abundant *Elaphomyces* species in eastern North America with a distribution extending from eastern Canada south through the eastern USA to northeastern Mexico. All six *Elaphomyces* species are putatively associated

with eastern hemlock, with *E. bartlettii* and *E. macrosporus* exclusively associated with that tree. Declines of eastern hemlock throughout the eastern USA, due to the introduced hemlock woolly adelgid, *Adelges tsugae* (Orwig *et al.* 2002), may reduce local diversity or abundance of *Elaphomyces* species. Additionally, we report partially consumed ascocata for four *Elaphomyces* species (*E. americanus*, *E. bartlettii*, *E. macrosporus*, and *E. verruculosus*). Moreover, these observations, coupled with rodent fecal samples containing spores of *E. bartlettii* and *E. oreoides*, suggest that small mammals and their predators play a key role in dispersing spores and increasing local diversity of *Elaphomyces* and that small mammals depend in part on the *Elaphomyces* as a food source.

MATERIALS AND METHODS

Ascocata were collected from 6 June to 5 October 2014 from Bartlett Experimental Forest, Northern Research Station, USDA Forest Service, New Hampshire, USA (44° 3' 7.2" N, 71° 17' 25.1" W; 250–435 m elevation). Additional ascocata were collected during directed searches in 2015 and ascocata that had been partially consumed by small mammals were collected opportunistically during 2014 and 2015. We sampled for ascocata on 12 established small mammal-trapping grids (105 x 105 m; 11 025 m²) stratified across hardwood (*n* = 4), softwood (*n* = 4), and mixed (*n* = 4) forest stands (R. Stephens, unpubl.). Within each 11 025 m² grid, we

sampled at 64 plots (4-m²; 16 plots each month) raked to a depth of 10 cm or until mineral soil was reached (Luoma & Frenkel 1991). In total, we sampled 768 4 m² plots across all grids (256 in each forest type). Hardwood forest stands were dominated by American beech, red maple (*Acer rubrum*), sugar maple (*A. saccharum*), yellow birch (*Betula alleghaniensis*), white birch (*B. papyrifera*), and white ash (*Fraxinus americana*), whereas softwood stands were dominated by eastern hemlock, red spruce (*Picea rubens*), and balsam fir (*Abies balsamea*). The coarse-loamy, well-drained soils are spodosols developed from glacial till and are underlain by granite (Schaller *et al.* 2010).

Colours are given in general terms, and not by reference to a colour chart. Ascomata were initially air dried in the field

and then thoroughly dried for 24–48 h at 60 °C in the laboratory. Dried specimens were rehydrated and examined in 3 % KOH, Melzer's reagent, and Cotton blue. Microscopic descriptions and micrographs are based on 3 % KOH mounts unless otherwise specified. Twenty ascospores were measured from the holotype collection of each species; dimensions include ornamentation. Dried ascospores from holotypes were mounted on aluminum pegs with double-sided tape and sputter coated with gold for scanning electron microscopy (SEM) with an AmRay 3300 FE field emission scanning electron microscope. Specimens were deposited in OSC (Oregon State University), FLAS (Florida State University), and BPI (US National Fungus Collection, Beltsville, MD).

***Elaphomyces americanus* Castellano, sp. nov.**

MycoBank 816067

(Fig. 1)

Etymology: “*americanus*”, describing the North American, particularly the eastern portion, distribution of this species.

Diagnosis: Differs from all North American species in the marbled inner peridium and from *E. muricatus* of Europe by being slightly smaller in overall spore size, having a coarser ornamentation with more lines than rods, and having a taller ornamentation.

Type: USA: West Virginia: Pocahontas Co., Middle Mt., Iron Bridge, 25 July 2001, S. Stephenson 14815 (OSC 81113 – holotype).

Description: Ascomata to 16 mm broad, more or less globose, completely embedded in a pale mycelial mat which forms a poorly to well-developed husk around individual ascomata incorporating soil, ectomycorrhizal roots, and debris; mycelium not staining when handled. Peridium overall 1.5–1.6 mm thick when mature, epicutis 500–600 µm thick,

of distinct, yellow-brown warts, most acutely pointed, some blunt, 4–5 sided, bases more or less contiguous, to 500 µm tall, 500–750 µm broad at the base, paler within and at the base, darker along the outline in section; inner layer ±1000 µm thick, marbled with veins which are white to off-white when young to pale brown when mature, matrix pale tan near surface grading to tan to brown to finally dark brown or black near the gleba, overall dark brown when mature, hyphal strands invaginating into the gleba from the inner peridium, pale tan to rose-tan to white to grey-brown, disintegrating at maturity. Gleba spore mass at maturity powdery, dark brown, with tan, spider web-like hyphae, when immature stuffed with bright white mycelium, then as spores form and mature the mycelium becomes off-white to pale grey. Odour indistinct, mild. Taste not recorded.

Peridium two-layered, outer (warty) layer of yellow-brown, compact, curly, contorted, agglutinated hyphae, walls ±2 µm broad, with a low wall of septate, hyaline, parallel hyphae between warts ±7 µm broad, walls ±3 µm thick, beneath the warts is a yellow-brown layer that rapidly grades into hyaline hyphae of a similar texture and size as the warts, then grading into a red-brown layer of similar texture except with amorphous pigmented granules scattered across the

C–H (OSC 8113 – holotype). Bars A = 1 mm, B = 5 mm, C = 500 µm, D–G = 10 µm, H = 5 µm.

layer, these dark areas in the inner layer matrix attributable to numerous pigment granules, macroscopically the entire area is dark making it difficult to determine the transition from white veins to dark veins. Gleba of spores and hyaline hyphae that are, smooth, septate, extensively branched, occasionally somewhat curly, loosely interwoven, 2–3 µm broad, walls <0.5 µm thick. Ascii globose, hyaline, 42–46 µm broad, walls 3–4 µm thick, 4–8-spored, arising from acrogenous hyphae which are puzzle-like, ±5 mm broad; spores with ascus smooth at first then soon with tall spines. Ascospores globose, 28–34 µm (mean = 30.9 µm) diam, ornamented, walls ±1 µm thick, brown in KOH when mature singly and in mass, ornamentation of tufts consisting of convalesced rods, not reticulate, 1.5–2.5 µm tall; with small, apparently aborted, globose spores measuring 16–17.5 µm broad.

Distribution, habit, habitat and season: Known from Canada (New Brunswick, Ontario, and Quebec) and the USA (Connecticut, Maine, Massachusetts, Michigan, New Hampshire, New York, North Carolina, Tennessee, Virginia, and West Virginia); hypogeous in sandy or clay soils; under *Abies balsamea*, *Picea rubens*, *Pinus banksiana*, *P. strobus*, and *Tsuga canadensis*; mainly June through October, but also found once in December.

Discussion: The marbled inner peridium separates this species easily from all other *Elaphomyces* species in North America. *Elaphomyces americanus* resembles *E. muricatus* from Europe, but the spores of *E. americanus* have a coarser ornamentation with more lines than rods, are slightly smaller, and have a taller ornamentation. The spores of *E. americanus* enlarge as they mature due to maturation of the ornamentation. The Canadian ascomata examined were younger and the spores in many specimens only 24–28 µm broad. Ascomata with a loose powdery gleba (the most mature specimens) have spores 28–32 µm broad.

Two specimens collected at Bartlett Experimental Forest on 11 Sept. 2015 (OSC 149823) and 21 July 2014 (OSC 149877) were partially consumed by small mammals. Both specimens had been excavated and discarded after consumption of most of the peridium, leaving the gleba exposed. Characteristics of the incisor marks on OSC 149877 indicate consumption by a red squirrel (*Tamiasciurus*

hudsonicus) or eastern chipmunk (*Tamias striatus*). In addition, collection OSC 149881 was also consumed in part and piles of spores were left on a fallen tree.

Beug *et al.* (2014) list "*E. americanum* nom. prov." which actually refers to this species.

Elaphomyces bartlettii Castellano & R.B. Stephens, sp. nov.

MycoBank 816068
(Fig. 2)

Etymology: For Bartlett Experimental Forest; named after Governor Josiah Bartlett (1729–1795), a New Hampshire politician and signer of the Declaration of Independence.

Diagnosis: Distinguished from *E. leveillei* and *E. morettii* of Europe by the dark brown hyphae that envelope the ascoma and spores which are coarse in ornamentation and 26.5–30 µm in size.

Type: USA: New Hampshire: Carroll Co., White Mountain National Forest, Bartlett Experimental Forest, 1.5 km south and 0.25 km east of the intersection of Bear Notch rd. and Hwy 302, 22 June 2015, R. Stephens & T. Remick (OSC 149816 – holotype; BPI 893241 – isotype).

Description: Ascomata subglobose to slightly lobed, to 22 mm broad x 17 mm tall, individual ascocarps enclosed in a well-developed husk incorporating dark brown hyphae, soil, ectomycorrhizal roots, and debris; hyphae not staining when handled. Peridium overall ±2 mm thick when mature, epicutis to 500 µm thick, of distinct, closely spaced, black warts, mostly bluntly rounded, variously shaped, to 200 µm tall, bases contiguous and to 250 µm broad, with abundant, dark brown hyphae packed between warts and often with a thin or thick layer of brown hyphae on wart apices, in section the outer layer appearing duplex because of the black warts and inter-wart dark brown hyphae; inner layer to 1.5 mm thick in places, off-white to pale tan, homogeneous (not marbled), pale tan hyphal strands invaginating into the gleba from the inner peridium. Gleba spore mass powdery, dark brown to black, scattered, pale tan, spider web-like hyphae, when immature gleba stuffed with bright white hyphae. Odour of garlic with an acrid component to skunk, extremely pungent and often detectable when surface soil is disturbed. Taste not recorded.

Peridium two-layered, outer (warty) layer of dark to nearly black, compact, septate, agglutinated, thick-walled (±2 µm broad), parallel hyphae, grading into dark brown then pale brown *textura epidermoidea*, of compactly interwoven hyphae, 4–7 µm broad, walls ±1 µm thick, between warts packed with dark brown hyphae arranged perpendicularly to the hyphae of the warts at times, these hyphae sometimes swollen, inner layer a *textura intricata*, of hyaline, septate, interwoven hyphae, 4–5 µm broad, to 12 µm broad when swollen, walls <0.5 µm thick, with abundant, large, amorphous crystalline particles scattered across the entire layer. Gleba composed of spores and hyphae, that are hyaline, smooth, septate, extensively branched, loosely interwoven, 2–4 µm broad. Ascii globose

with a stout pedicel, ±60 µm broad, walls 1–2 µm thick, hyaline, 8-spored. Ascospores globose, often with some slightly flattened sides, 26.5–30 µm (mean = 27.7 µm) diam, ornamented; walls ±1 µm thick, in KOH dark brown to black when mature both singly and in mass, ornamentation 1–2 µm tall, appearing as a dimpled or punctate surface with scattered smooth areas, spores can be somewhat coarse looking in cross-section, particularly the darker spores; in SEM with a fine-structured reticulum overlain with patches of flattened, plate-like material.

Distribution, habit, habitat and season. New Hampshire; hypogeous in humic soils, scattered to gregarious; under *Tsuga canadensis*; June through October.

Other collections examined: USA: New Hampshire: Carroll Co., White Mountain National Forest, Bartlett Experimental Forest, 1.5 km south and 0.25 km east of the intersection of Bear Notch rd. and Hwy 302, 21 Sept. 2014, R. Stephens & T. Remick (OSC 149804, BPI 893240); same data except 2.8 km south and 0.06 km west of the intersection of Bear Notch rd. and Hwy 302, 7 June 2014 (OSC 149797); same data except 3 Aug. 2014 (OSC 149805); same data except 30 June 2014 (OSC 149818); same data except 14 Sept. 2014 (FLAS-F59190); same data except 2.25 km south and 0.75 km east of the intersection of Bear Notch rd. and Hwy 302, 14 Aug. 2015 (OSC 149817); same data except 2 km south and 1.4 km west of the intersection of Bear Notch rd. and Hwy 302, 28 Sept. 2014 (OSC 149819); same data except 2.25 km south and 0.8 km west of the intersection of Bear Notch rd. and Hwy 302, 8 July 2014 (OSC 149820); Strafford Co., Durham, East Foss Farm, 1 km south of the intersection of Mill rd. and Foss Farm rd., 2 Oct. 2016, R. Stephens & K. Kwasnik (OSC 150062).

Discussion: Immature ascocarps of *Elaphomyces bartlettii* have a bright white inner peridium which grades to off-white towards the centre at maturity. The interior is initially hollow, filling with white cottony hyphae, becoming black and powdery as the spores develop and mature. *Elaphomyces bartlettii* bears some resemblance to *E. leveillei* and *E. morettii* from Europe. The ascocarps of *E. leveillei*, however, are covered with a greenish mycelium and a green mycelium patch persists at the base after handling. *Elaphomyces leveillei* has similar sized spores but the ornamentation appears smoother in cross-section and under SEM (not shown). The ascocarps of *E. morettii* have a brownish red mycelium and spores which are much smaller (17–22 µm) and have a coarser ornamentation.

One specimen collected at Bartlett Experimental Forest on 30 June 2014 (OSC 149818) was partially consumed by a small mammal. The mature ascocarp was left *in situ* at a depth of approximately 7 cm. Soil was excavated to reach the ascocarp and animal activity had left the gleba partially exposed. Additionally, spores of *E. bartlettii* were detected in fecal samples from a southern red-backed vole (*Myodes gapperi*) and *T. striatus* live-trapped at Bartlett Experimental Forest. The *M. gapperi* sample was collected on 3 Aug. 2014 just 17 m from OSC 149817, and the *Tamias striatus* sample was collected on 1 July 2014 approximately 90 m from OSC 149820.

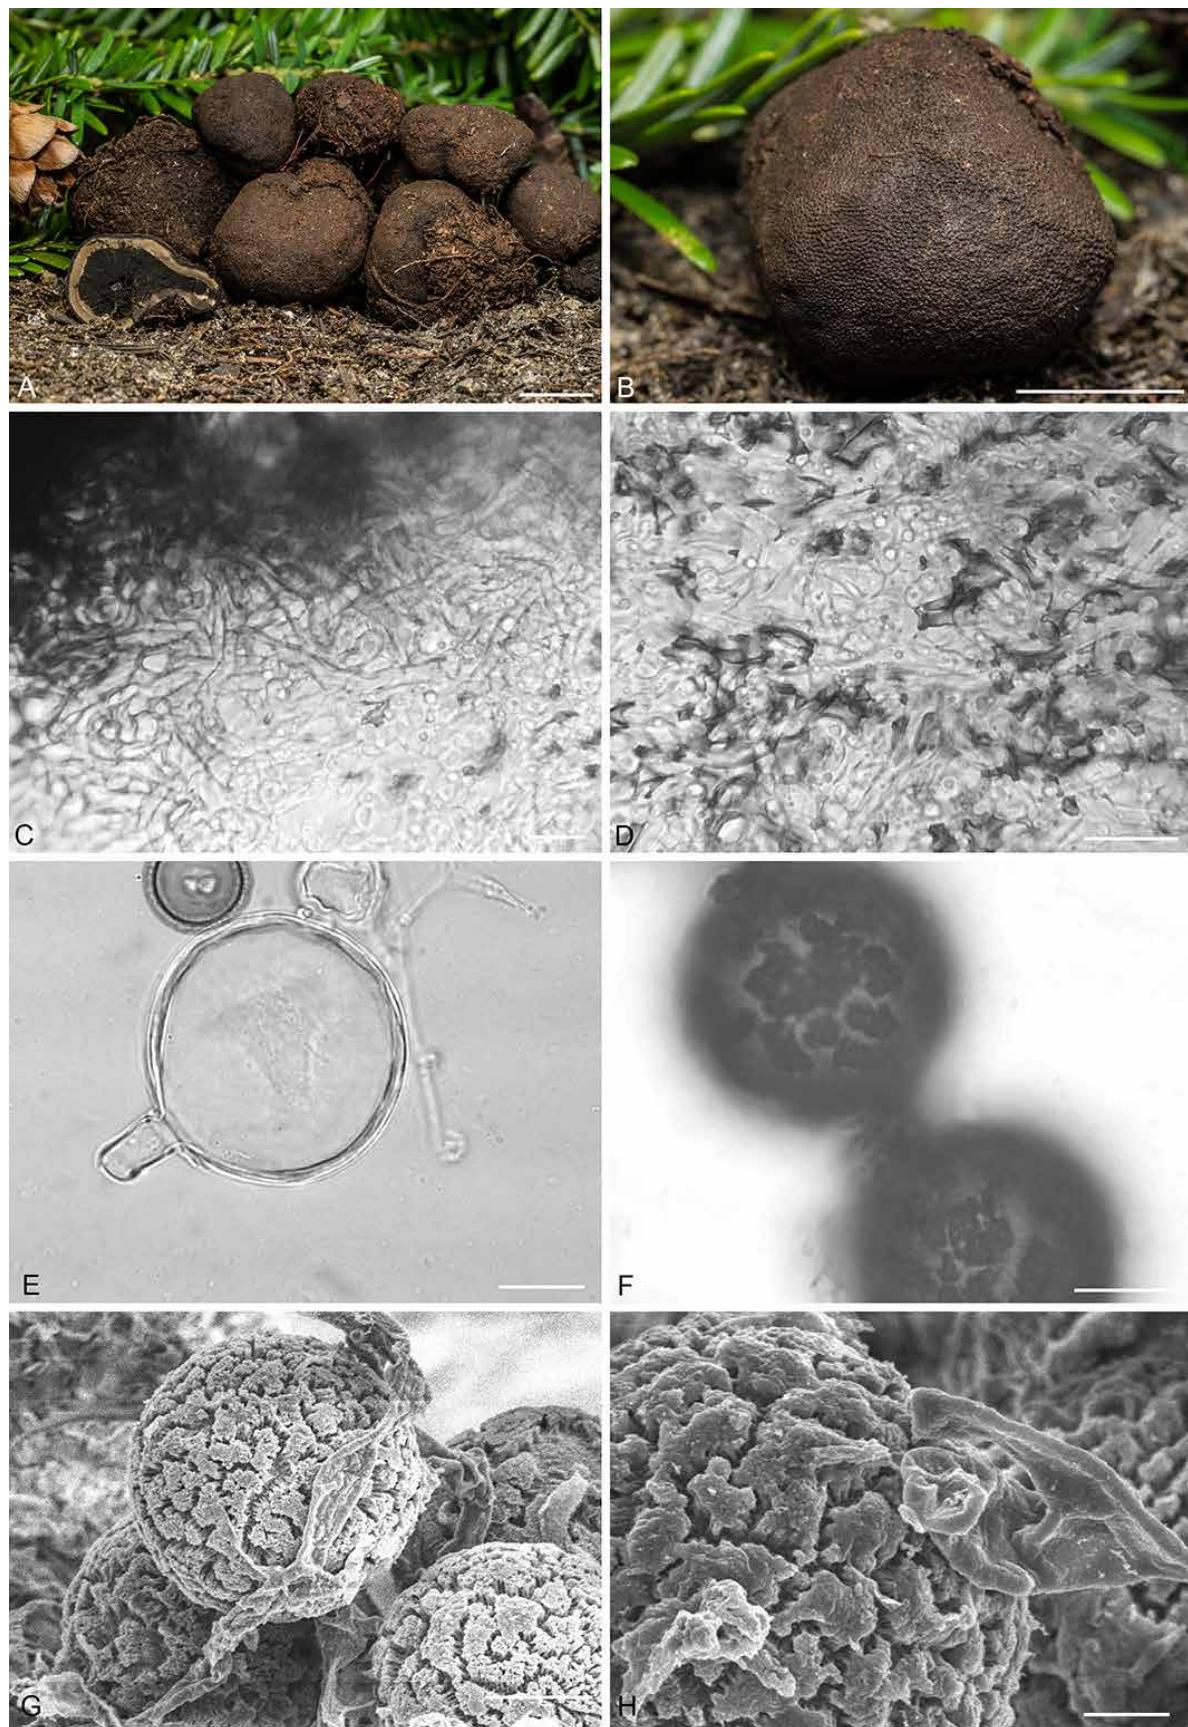

Fig. 2. *Elaphomyces bartlettii*. **A.** Ascomata showing peridial surface, gleba, and peridium in section. **B.** Ascoma showing small warts on peridial surface. **C.** Epicutis with the darker outer area grading into a paler inner area. **D.** Subcutis with abundant amorphous, crystalline particles scattered across the layer. **E.** Thick-walled, pedicellate ascus. **F.** Ascospores in surface view showing the clumpy ornamentation. **G.** Scanning electron micrograph of ascospores showing the labyrinthine pattern to the clumpy ornamentation. **H.** Scanning electron micrograph showing the fine detail of the ornamentation. A–H (OSC 149816 – holotype). Bars A, B = 10 mm, C–E = 20 µm, F, G = 10 µm, H = 5 µm.

Elaphomyces macrosporus Castellano & T.F. Elliott,
sp. nov.
MycoBank 816070
(Fig. 3)

Etymology: “*macrosporus*” *macro* – large, *sporus* – spore, in reference to the large spores.

Diagnosis: This species differs from other *Elaphomyces* species by its large spores which are ornamented with rods and clumps of rods that form broad based cones or ridges and the black hyphae that cover the brown peridial warts.

Type: USA: West Virginia: Tucker Co., Canaan Heights, along Hwy 32, south of Davis, 6 July 2015, M. Castellano (OSC 149891 – holotype).

Description: Ascomata to 2 cm broad, irregular, often completely enveloped in a dark sordid yellow mycelium, organic debris, and ectomycorrhizal roots, occasionally ascomata are dislodged from the substrate without adherent mycelium, debris and roots; mycelium not staining when handled; base with yellow mycelial tuft. Peridium to 1000 µm thick, outer surface of yellow-brown warts ±200 µm tall by 160–200 µm broad at the base, warts embedded in a black mycelium to give the appearance of a black ascoma with dark yellow-brown dots that are the tips of the warts emerging from the black mycelium, subcutis ±800 µm thick, uniform, grey, leathery, homogeneous (not marbled). Gleba spore mass powdery, dark brown to black at maturity, with dark spider web-like hyphae, when immature gleba of stuffed bright white hyphae and pale brown tissue. Odour initially a faint hint of citrus, increasing as ascomata begin to decay underground. Taste not recorded.

Peridium two-layered, epicutis, ±200 µm thick, of compact, septate, yellow-brown, disorganized, compact hyphae, ±5 mm broad, walls ±1 µm thick; subcutis ±800 µm thick, composed of hyaline, septate, compact, interwoven hyphae, to 10 µm broad, walls ±1 µm thick; also an ill-defined inner layer of pale tan, loosely interwoven hyphae, to 4 mm broad near the gleba. Ascii subglobose to globose with a stipitate base, 48–53 µm broad, walls ±2.5 µm thick, hyaline, 4- or 8-spored, stipitate base to 11 µm long. Ascospores globose, (39.5–) 41–44(–45.5) µm (mean = 42.2 µm) diam, ornamented, walls ±1 µm thick, in KOH singly and in mass dark brown to red-brown when mature, ornamentation of rods and clumps of rods that form broad based cones or ridges, to 3 µm tall, immature spores abundant, dense, dark red-brown, 20–30 mm broad.

Distribution, habit, habitat and season: Known from Maine, Massachusetts, New Hampshire, North Carolina, and West Virginia; hypogeous, usually clustered; under *Tsuga canadensis*; June through November.

Collections examined: USA: Maine: Cumberland Co., Bradbury Mountain State Park, at campground, 17 Oct. 2015, R. Stephens (OSC 149827); Massachusetts: Hampshire Co., University of Massachusetts campus, near Brown Dormitory, 10 Aug. 1986, M. Castellano (OSC 149882); Worcester Co., Wachusett Mountain, 16

Nov. 1984, J. Trappe (OSC 149112); New Hampshire: Carroll Co., White Mountain National Forest, Bartlett Experimental Forest, 1.5 km south and 0.25 east of the intersection of Bear Notch rd. and Hwy 302, 17 June 2014, R. Discussion: “*Elaphomyces macrosporus* nom. prov.” was listed by Beug *et al.* (2014) and had been previously identified as *E. leveillei* by Loeb *et al.* (2000) from North Carolina. The peridial surface of *Elaphomyces macrosporus* resembles that of *E. aculeatus* from Europe which has much smaller spores (21–24 µm broad). The peridial surface and spore ornamentation of *E. spinoreticulatus* (Zhang & Minter 1989) is also similar to *E. macrosporus* but *E. spinoreticulatus* spores are demonstrably smaller (35–38, mean = 36.1 µm) than *E. macrosporus* spores (41–44, mean = 42.2 µm). *Elaphomyces macrosporus* is also similar (macroscopically and in spore characteristics) to *E. verruculosus* and both occur in eastern North America. *Elaphomyces verruculosus* lacks any black mycelium surrounding the brown peridial warts and on average the spores are smaller (36–45 µm, mean = 41.1 µm broad) and have a more coarse appearance. Immature ascomata of *E. macrosporus* have a bright white inner peridium which grades to pale tan towards the gleba at maturity, often creating a two-tone appearance. The gleba of immature ascomata is solid and white, becoming black and powdery as the spores mature.

Two specimens collected at Bartlett Experimental Forest on 2 Aug. 2014 (OSC 149825) and 3 Aug. 2015 were partially consumed by small mammals. The peridium of OSC 149825 (maturing specimen) was partially consumed. The soil was

A, B (OSC 149890); C–F (OSC 149891 – holotype); G, H (OSC 149802). Bars A = 1 cm, B = 5 mm, C–G = 20 μ m, H = 10 μ m.

excavated to reach the ascoma at a depth of approximately 3 cm; the ascoma was left *in situ*. The peridium and gleba of OSC 149826 (immature specimen) were consumed and left *in situ* at approximately 3 cm.

Elaphomyces oreoides Castellano, sp. nov.

MycoBank 816071

(Fig. 4)

Etymology: “*oreoides*”—resembling Oreo, in reference to the resemblance of the profile of an Oreo cookie with three inner peridial layers, dark/light/dark, in addition to the slightly sweet odor.

Diagnosis: Differs from other eastern North American species of the genus by having yellow-brown spores with a complete reticulum ornamentation and the inclusion of ectomycorrhizas within the lower portion of the inner peridium. It differs from the *E. persoonii* of Europe by the brown mycelium surrounding ascocarps.

Type: USA: North Carolina: Buncombe Co., milepost 385.5 along Blue Ridge Parkway, 4 Sept. 1994, M. Castellano, Z. Miller & W. Miller (OSC 58219 – holotype).

Description: Ascomata to 22 x 27 mm diam, subglobose, often with broad irregular pits, flattened to somewhat turbinate, with a persistent, large basal tuft, to 19 mm broad where attached, 6–7 mm long, composed of a tangle of dark yellowish grey to brown mycelium, ectomycorrhizal roots, soil particles, and debris; dense pale brown to dark brown to greyish black mycelium adherent to the entire peridial surface; mycelium not staining when handled, unchanged when dried. Peridium subcartilaginous, 1.2–3.0 mm thick, four-layered, somewhat zonate with a very dark outer layer underlain by a medium-dark layer grading into a more or less hyaline layer with occasional pale tan streaks, underlain by another dark hyphal layer adjacent to the gleba; outer surface 200–250 µm thick, very dark brown, carbonaceous, of mostly flattened, irregularly shaped or plate-like warts, to 0.5 mm broad at the base, warts simplex in structure, warts larger at the ascoma apex, smaller along the sides and near the base, often nearly smooth near the base; three inner layers 1–2.75 mm thick combined, inner layers uneven in thickness, zonate to somewhat mottled, the middle layer off-white to pale tan, exterior of the inner layers brown; numerous ectomycorrhizas embedded within the inner two layers closest to the gleba, concentrated in the lower half of the specimen, more numerous at the base, absent at the ascoma apex. Gleba spore mass powdery, very dark blue-grey, off-white, spider web-like hyphae invaginating from the inner peridial layer into the gleba towards the centre, thicker patches of off-white hyphae scattered around the gleba-peridium interface from which the spider web-like hyphae emerge. Odour slightly sweet. Taste not recorded.

Peridium four-layered, outer layer 200–250 µm thick, of dark brown, short-segmented, compact hyphae, 3–7 µm broad, to 20 µm long, walls 1–2 µm broad, grading into the

first inner layer, 250–500 µm thick, composed of brown, compact hyphae, 3–7 µm broad, arranged in a *textura intricata*, walls ±1 µm thick; middle inner layer, 250–1000 µm thick, composed of hyaline, compact hyphae, 2–3 µm broad, arranged in a *textura porrecta*, walls <0.5 µm thick, occasional streaks of pale brown hyphae present in this middle inner layer; third inner layer (closest to the gleba) 500–2000 µm thick, composed of brown, compact hyphae, to 10 µm broad, arranged in a *textura epidermoidea*, walls ±1 µm broad, somewhat restricted in diameter at the septa. Gleba composed of spores and thin-walled, hyaline, septate, sinuous to curly, slightly encrusted hyphae, ±4 µm broad. Ascii globose to irregularly globose (from pressure of enlarging spores), 65–80 µm broad, walls 0.5 µm thick, 8-spored. Ascospores globose, (27–)28–30(–31) µm (mean = 29.3 µm) diam, ornamented, walls ±1 µm thick, in KOH singly and in mass yellow-brown when mature, ornamentation a complete reticulum with coarse projections at the top of the alveoli, to 2 µm tall, alveoli to 5 µm broad.

Distribution, habit, habitat and season: Known from New Hampshire, North Carolina, and West Virginia; hypogeous, single to clustered; under *Betula alleghaniensis*, *Carya* sp., *Fagus grandifolia*, *Gymnocladus dioicus*, *Pinus resinosa*, *P. strobus*, *Quercus prinus*, *Q. ruber*, *Q. virginiana*, and *Tsuga canadensis*; June, September, and October.

Collections examined: USA: New Hampshire: Carroll Co., White Mountain National Forest, Bartlett Experimental Forest, 2.25 km south and 0.8 west of the intersection of Bear Notch rd. and Hwy 302, 8 June 2014, R. Stephens & T. Remick (OSC 149798, FLAS-F59191); North Carolina: Buncombe Co., Mountain to Sea trail, 1 Sept. 1991, W. Sturgeon (OSC 149105); milepost 383.5 along Blue Ridge Parkway, 4 Sept. 1994, M. Castellano, J. Roberts, G. Semlak, J. Shubzda & P. Perret (T13589); Haywood Co., Great Smokey Mountain National Park, near summit of Purchase Knob, 22 Sept. 2012, T. Elliott (OSC 149100); Rutherford Co., off Painters Gap rd., 23 Sept. 2007, T. Elliott (OSC 149248); West Virginia: Barbour Co., Laurel Mountain, 16 Oct. 1997, D. Mitchell 597 (OSC 149102).

Discussion: *Elaphomyces oreoides* resembles *E. persoonii* from Europe in the possession of a basal tuft of mycelium, a dark brown to black, warty peridium and reticulate spores. *Elaphomyces persoonii* has a green mycelium covering the ascocarps whereas *E. oreoides* has a brown mycelium.

Spores of *E. oreoides* were detected in the fecal samples of two woodland jumping mice (*Napaeozapus insignis*) live-trapped at Bartlett Experimental Forest. These *N. insignis* were trapped on 4 June 2014 and 30 July 2014 on the same grid where the ascocarps of *E. oreoides* (OSC 149798, FLAS-F59191) was collected. One additional collection, OSC 149405, is parasitized by an unidentified *Tolypocladium* species.

Beug *et al.* (2014) list “*E. fallax* nom. prov.” which is actually this species.

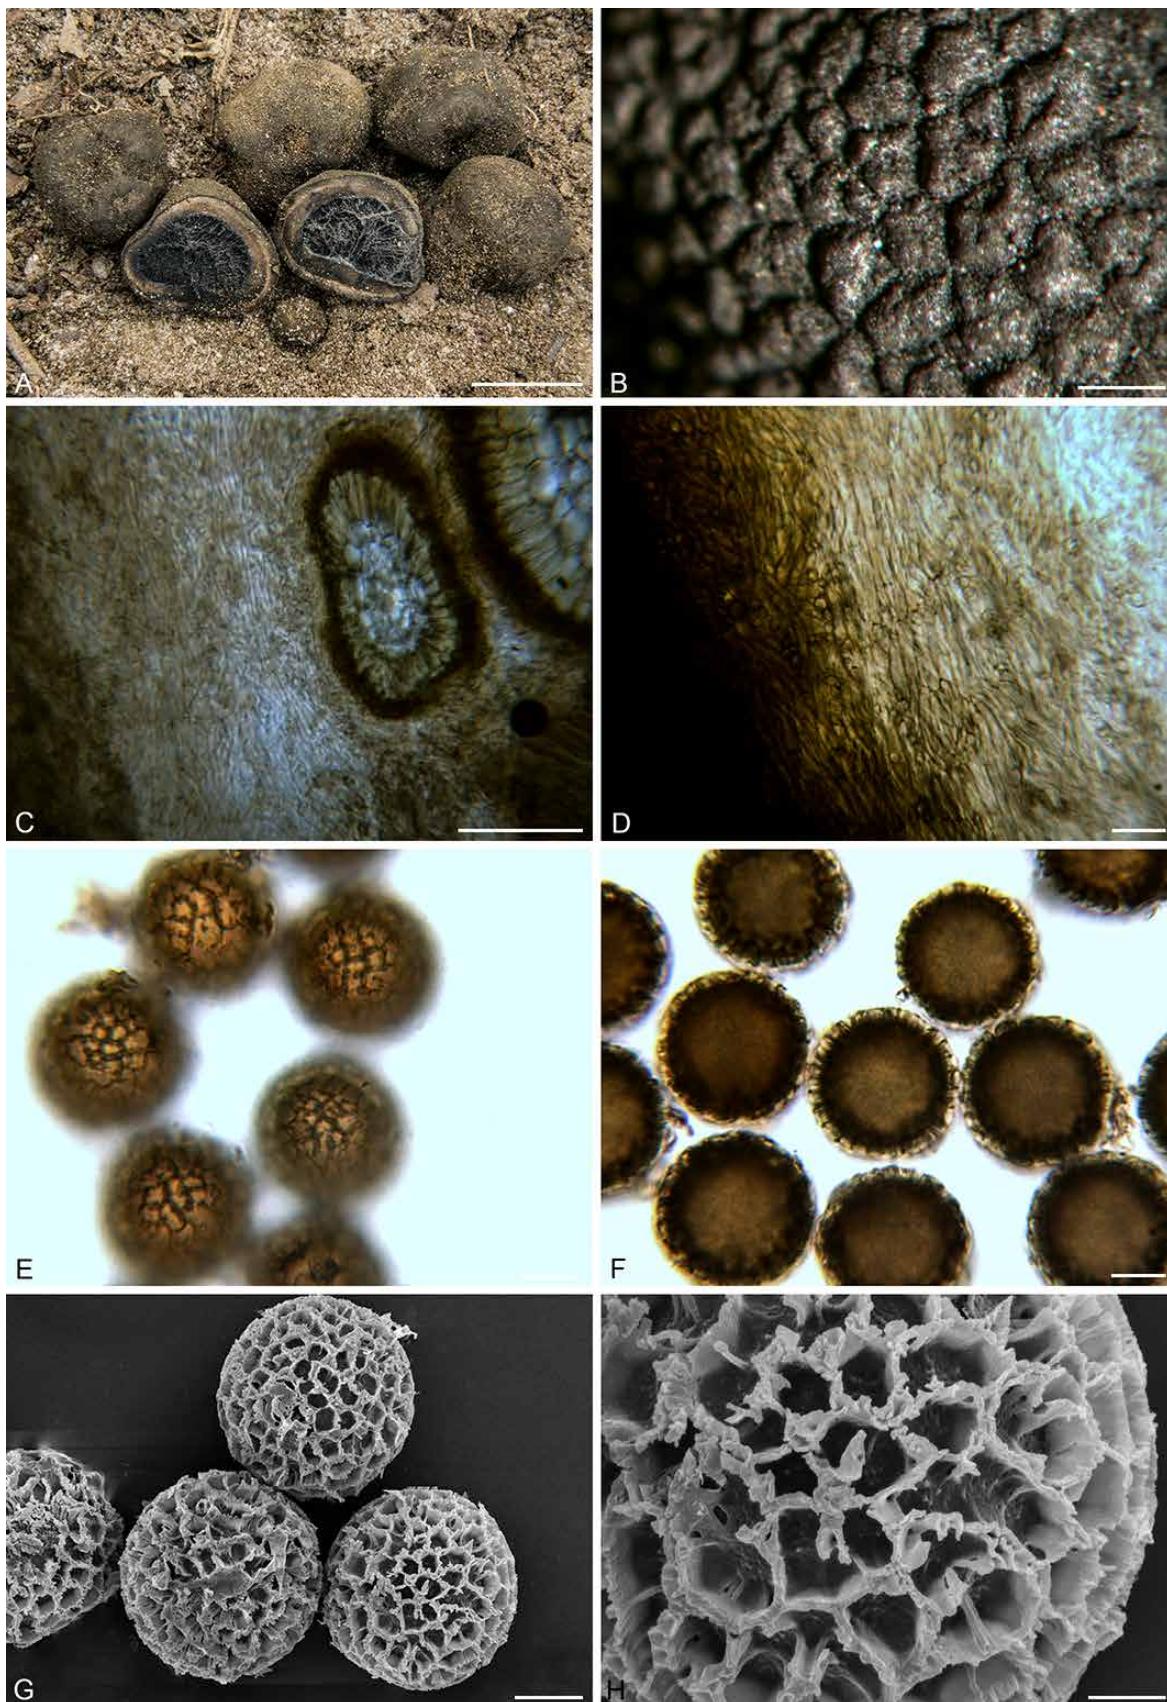

Fig. 4. *Elaphomyces oreoides*. **A.** Ascocarps showing peridial surface, gleba, and peridium in section (OSC 149248, photo T.F. Elliott). **B.** Surface of the peridium showing the warts. **C.** Ectomycorrhizas embedded within the inner peridium. **D.** Outer peridium showing the gradation of the dark-colored outer hyphae into the paler colored inner hyphae. **E.** Ascospores with ornamentation in surface view showing the reticulate pattern of the ornamentation. **F.** Ascospores in cross-sectional view showing the height and pattern of the ornamentation. **G.** Scanning electron micrograph of ascospores. **H.** Scanning electron micrograph of ascospores showing the fine detail of the ornamentation. B–H (OSC 149979). Bars A = 20 mm, B, C = 500 µm, D = 20 µm, E–G= 10 µm, H = 5 µm.

Elaphomyces remickii Castellano & R.B. Stephens, sp. nov.
MycoBank 816072
(Fig. 5)

Etymology: Named for Tyler J. Remick, undergraduate student who aided R. Stephens immensely with collection and preparation of mycological samples at Bartlett Experimental Forest.

Diagnosis: Distinguished by the medium brown gleba, unusual in the genus, at maturity, tall pyramidal warts on peridial surface, and the hyaline to pale tan spore colour at maturity.

Type: USA: New Hampshire: Carroll Co., White Mountain National Forest, Bartlett Experimental Forest, 1.5 km south and 0.25 km east of the intersection of Bear Notch rd. and Hwy 302, 15 July 2014, R. Stephens & T. Remick (OSC 149814 – holotype).

Description: Ascomata subglobose, to 20 mm broad x 12 mm tall. Peridium overall 1250–1850 µm thick when mature, in surface view wart tips variably-shaped, emerging from dense, brown hyphal layer between warts, warts acute, brown, pyramidal-shaped overall, bases contiguous, base to 250–300 µm broad, many smaller, in section warts red-brown in outline, yellow at the base, with abundant, brown hyphae packed between the warts; inner layer homogeneous (not marbled), 1.0–1.5 mm thick in places, mostly off-white but occasionally somewhat tan near gleba, pale tan hyphal strands invaginating into the gleba from the inner peridium. Gleba spore mass powdery, medium brown, scattered, white, hyphal strands invaginating from the inner peridium into the gleba and reaching the centre. Odour not recorded. Taste not recorded.

Peridium two-layered, outer (warty) layer of yellow-red-brown, compact, septate, agglutinated, stacked hyphae forming a *textura prismatica*, 6–8.5 µm broad, walls 2–3 µm broad, hyphae between the warts arranged in a tightly stacked manner, sometimes perpendicular to the hyphae within warts, of hyaline, septate, compact hyphae, 3–4 µm broad, walls ±1 µm thick, inner layer a *textura epidermoidea*, of hyaline, compact, tangled hyphae, 4–5 µm broad, walls ±1 µm broad. Gleba of spores of hyaline, smooth, septate, extensively branched, loosely interwoven hyphae, 2–4 µm broad, walls 0.5 µm thick. Ascii not seen. Ascospores globose, 31–35 µm (mean = 33.2 µm) diam, ornamented, walls ±1 µm thick, in KOH hyaline to pale tan at maturity singly and in mass, ornamentation to 1 µm tall, appearing as a compact undulate surface, in cross-sectional view lumpy; in SEM appearing as a coarse, rugose spore surface.

Distribution, habit, habitat and season: Known only from a single locality in New Hampshire; hypogeous in humic soils, clustered; under *Abies balsamea*, *Betula alleghaniensis*, or *Tsuga canadensis*; July.

Discussion: Macromorphological characteristics of *Elaphomyces remickii* are unusual in the genus due to the medium brown, powdery spore mass and the tall, pyramidal warts of the peridial surface.

Elaphomyces verruculosus Castellano, Rev. Mex. de Micol. 35: 19 (2012).
(Fig. 6)

Description: Ascomata irregularly subglobose to reniform, to 22 x 27 mm. Peridial outer surface of semi-rounded to angular or elongate warts, to 500 µm wide and 300 µm tall, rounded to acute or even flattened at the apices, contiguous with each other at the base. Pale yellow-brown when young then mottled brown and yellow-brown when mature with much pale brown, brown or yellow-brown hyphae, soil and debris covering the warts. Warts often obscured by inter-wart hyphal structures making the surface appear nearly smooth or papillate; in section warts are outlined with a ±140 µm thick layer of red-brown to dark red-brown cells underlain with paler yellow-brown to off-white tissue, 300–350 µm thick. Below at the base of the warts there is an off-white layer sometimes tinged pale grey-blue; subcutis to 2 mm broad, off-white to pale grey, uniform (not marbled) or sometimes zoned off-white above and pale grey or pale grey-tan below, more readily apparent on mature specimens; often a distinct, brown layer, ±100 µm thick present at the interface with the gleba. This layer is contiguous and concolorous with the dissepiments that invaginate into the gleba. Gleba off-white and cottony when immature, then the spore mass becoming powdery, dark brown to nearly black when mature, numerous pale grey to brown mycelial strands arising from the inner peridial wall and traversing the gleba. Odour indistinct to musky or skunky. Taste of mild cultivated mushrooms.

Peridium inter-wart spaces filled with hyaline, pale yellow to pale yellow-brown, septate, parallel hyphae 3–8 µm broad, walls 2–3 µm thick, also at times covering the wart apices; overall the peridium is two-layered, epicutis a warty layer, ±450 µm broad, with a red to red-brown layer near the wart surface then yellow-brown then grading to off-white near the wart base, composed of compact, interwoven hyphae 3–8 µm broad, similar in structure to the inter-wart hyphae and sometimes contiguous in organization but not in colour; subcutis to ±2 mm broad, also similar in structure to the outer inter-wart layer except that the hyphae are hyaline with amorphous, hyaline granules or pigments interspersed across this layer, the scattered granules much less dense near the gleba and dark grey or dark red-brown. Gleba constituted of spores and hyaline, septate, smooth or slightly encrusted, sinuous, loosely interwoven hyphae, to 5 µm broad, walls 1–1.5 µm thick. Ascii globose, hyaline, 42–50 µm broad, (2–)4–8-spored, walls ±2 µm thick, arising from acrogenous hyphae of clustered knots of hyaline, short-segmented hyphae, ±3 µm broad, walls ±1 µm thick. Ascospores globose, (35–)36–45(–46) µm broad (mean = 41.1 µm) diam, ornamented; in KOH brown to red-brown to dark red-brown singly and in mass; walls ±1 µm thick; ornamentation of tall, hyaline spines or rods when immature (in ascii), of dense rods and tufts of rods when mature, 2–3 x 2–3 µm, giving the spore surface a more or less coarse appearance, appearing fuzzy in section, as spores mature they darken and the tufts become darker and more distinct, mature spores dark red-brown and appearing much more coarse, aborted spores (23–28 µm broad) present and much darker.

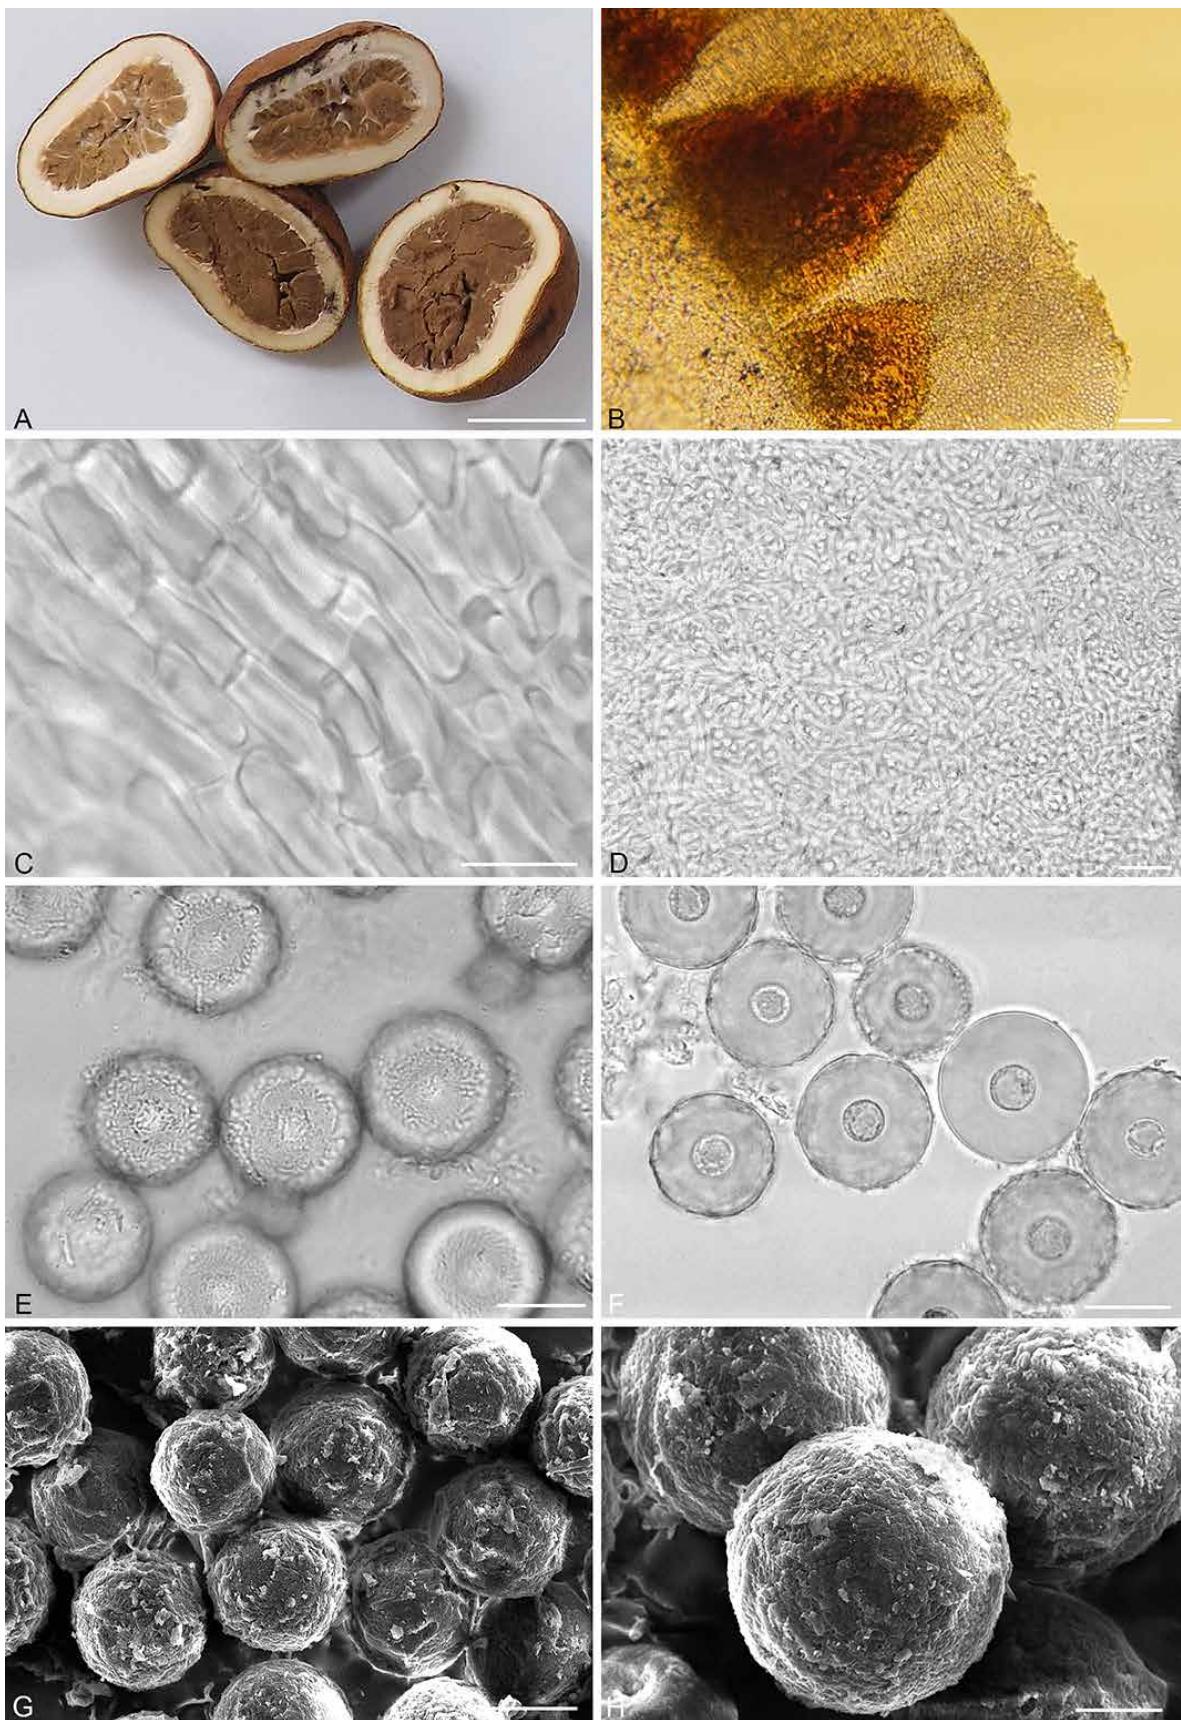

Fig. 5. *Elaphomyces remickii*. **A.** Ascomata showing gleba and peridium in section. **B.** Outer peridial layer showing the dark coloured tissue of the warts embedded within pale stacked hyphae. **C.** Pale, thick-walled, stacked hyphae occurring between wart tissue. **D.** Inner peridial tissue forming a *textura epidermoidea*. **E.** Ascospores with ornamentation in surface view showing the undulate pattern of the ornamentation. **F.** Ascospores in cross-sectional view showing the height and pattern of the ornamentation. **G.** Scanning electron micrograph of ascospores. **H.** Scanning electron micrograph of ascospores showing the fine detail of the ornamentation. A–H (OSC 149814 – holotype). Bars A = 10 mm, B = 50 µm, C = 10 µm, D–G = 20 µm, H = 10 µm.

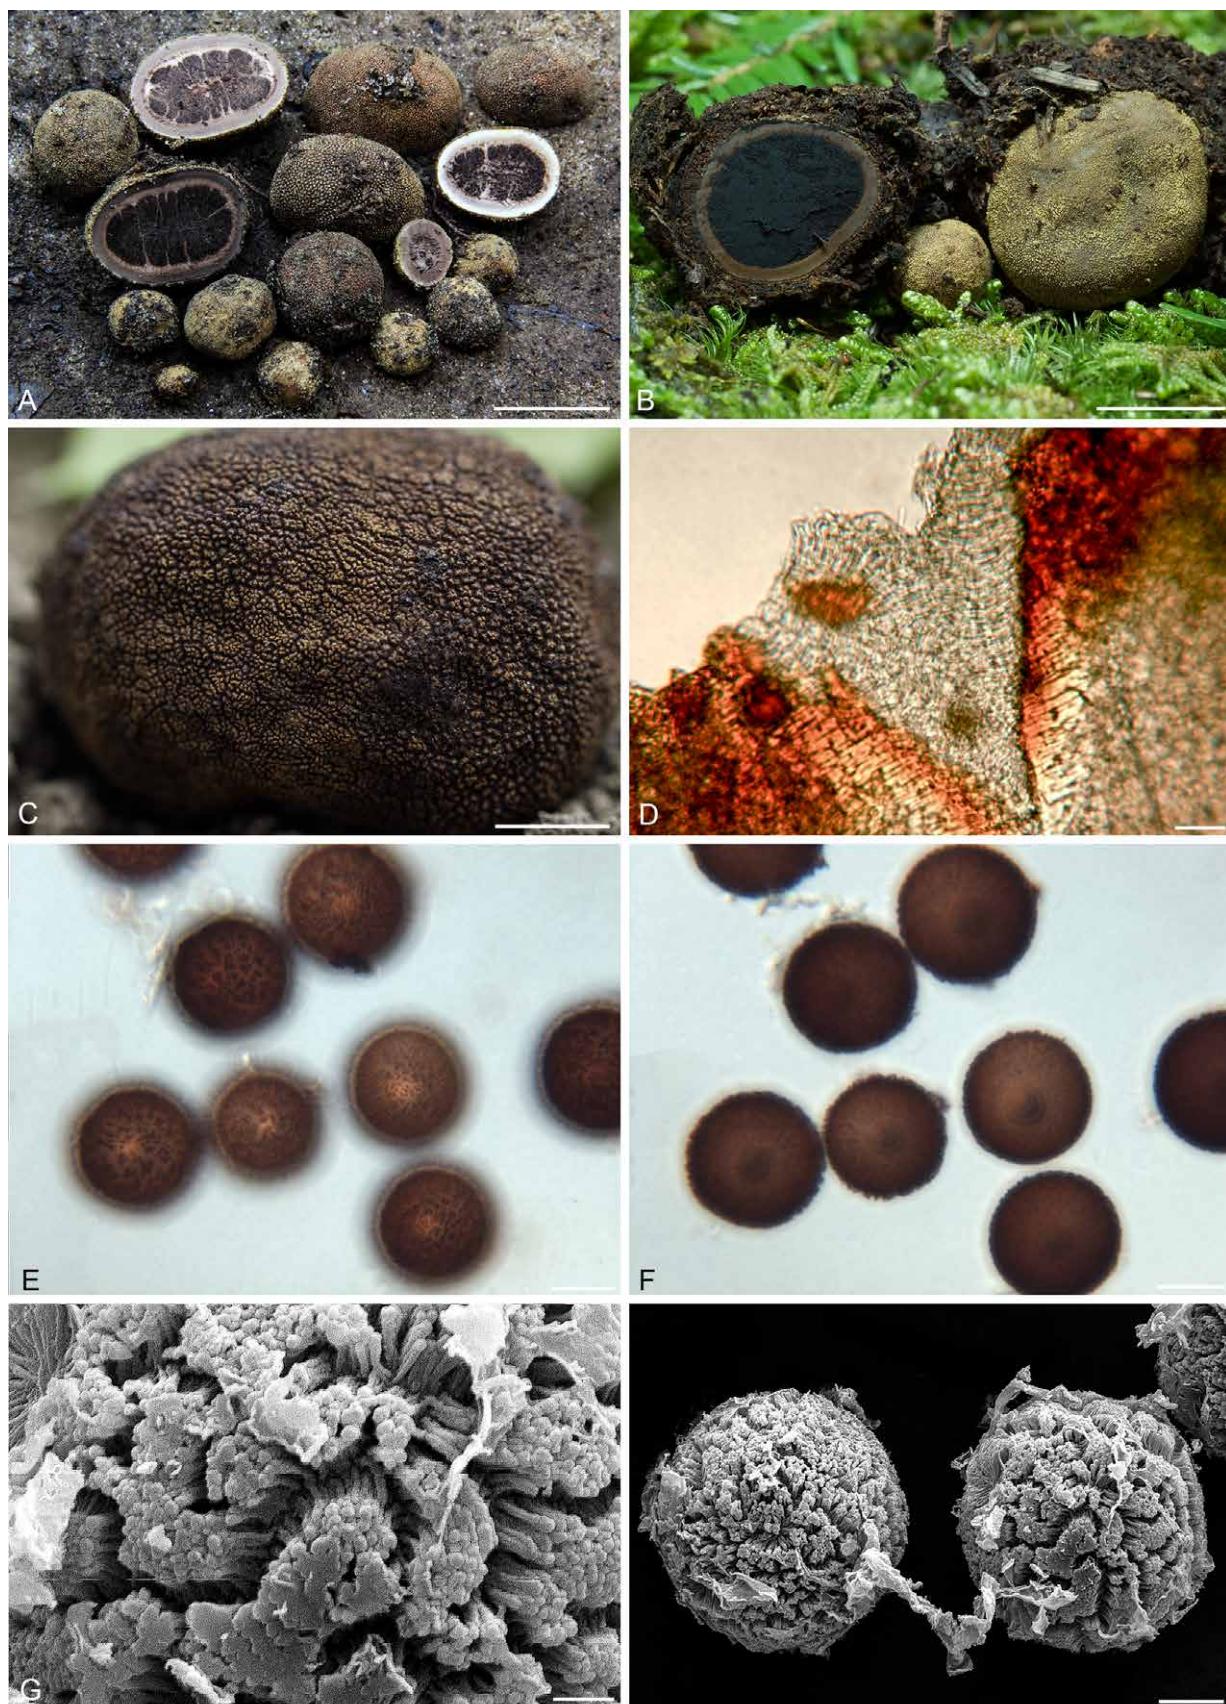

Fig. 6. *Elaphomyces verruculosus*. **A.** Ascomata showing peridial surface, gleba, and peridium in section (OSC 150012, photo T.F. Elliott). **B.** Ascomata embedded in ectomycorrhizas, soil, and debris; shown in surface and cross-section view (OSC 150013). **C.** Ascoma showing the peridial surface in finer detail. **D.** Outer peridium showing the pale, stacked hyphae between the darker coloured wart tissue. **E.** Ascospores with ornamentation in surface view showing the rods and spines of the ornamentation. **F.** Ascospores in cross-sectional view showing the height and pattern of the ornamentation. **G.** Scanning electron micrograph of ascospores showing the fine detail of the ornamentation. **H.** Scanning electron micrograph of ascospores. D–F (OSC 49670); C, G, H (OSC 48377). Bars A = 20 mm, B = 15 mm, C = 5 mm, D = 30 µm, E–F = 20 µm, G = 1 µm, H = 10 µm.

Distribution, habit, habitat and season: Known from Quebec, Canada south to Florida and northeastern Mexico; hypogeous, single to clustered; under *Fagus grandifolia*, *Picea abies*, *P. rubens*, *Pinus elliotii*, *P. palustris*, *P. pungens*, *P. resinosa*, *P. strobus*, *P. taeda*, *P. virginiana*, and *Tsuga canadensis*; June through October but also found once in December.

Collections examined: USA: New Hampshire: Carroll Co., White Mountain National Forest, Bartlett Experimental Forest, 2.5 km south and 1.7 km west of the intersection of Bear Notch rd. and Hwy 302, 4 Oct. 2014, R. Stephens & T. Remick (OSC 149806, 149807, 149808); same data except (OSC 149879); same data except 2.8 km south and 0.06 km west of the intersection of Bear Notch rd. and Hwy 302, 2 Aug. 2014 (OSC 149809); same data except 6 June 2014 (BPI 893249); same data except 2.5 km south and 0.5 km east of the intersection of Bear Notch rd. and Hwy 302, 15 Aug. 2014 (OSC 149810), same data except 2.8 km south and 0.35 km west of the intersection of Bear Notch rd. and Hwy 302, 31 July 2014 (OSC 149831); same data except 2.25 km south and 0.8 km west of the intersection of Bear Notch rd. and Hwy 302, 8 July 2014 (FLAS-F59193); Rockingham Co., Kwaks Sanctuary, Audubon Society land on Route 152, 1.5 miles west of intersection with Route 108, in Newmarket, 26 Dec. 2015, R. Stephens & K. Kwasnik (OSC 150009).

Discussion: This species was described by Castellano *et al.* (2012b) from Connecticut, Georgia, Louisiana, Massachusetts, Mississippi, New York, North Carolina, Vermont, Virginia, West Virginia, northeastern Mexico, and Quebec in Canada. This is the most commonly encountered and abundant *Elaphomycetes* species in eastern North America.

On a sampling grid dominated by old growth *Tsuga canadensis* at Bartlett Experimental Forest, 80 % (51 of 64) of the 4 m²-plots had ≥ 1 ascocarps (collections including: OSC 149806, 149807, 149808, 149879). On another grid, one sampling plot had 173 sporocarps in 4 m² (BPI 893249). The abundance of this species may make it an important food source for small mammals. Vernes & Poirier (2007) found *E. verruculosus* cashed by a *Tamias hudsonicus* in a bird's nest in New Brunswick, Canada. We found an air-drying ascoma (OSC 149831) on a broken-off snag which was putatively placed there by a *T. hudsonicus* based on the incisor marks. Additionally, we found a single ascoma on 21 June 2014 (OSC 149879) with incisor marks from a vole or mouse-sized small mammal.

The warty, brown, leathery peridial surface and off-white to pale grey, homogeneous inner peridial layer (occasionally tinged bluish) in cross-section clearly distinguish *E. verruculosus* from other *Elaphomycetes* species in North America. It is similar to *E. granulatus* from Europe, but *E. granulatus* has somewhat smaller spores (35–41 µm, mean = 37.9 µm) and a coarser pattern to the ornamentation of agglutinated rods and spines that form larger patches. The statements about spore size in *E. granulatus* in Castellano *et al.* (2012b) are erroneous.

ACKNOWLEDGMENTS

We thank Steve Miller (University of Wyoming), Susan Loeb (US Forest Service, South Carolina), Todd F. Elliott (North Carolina), Frances Marzitelli (Quebec), and Donna Mitchell (West Virginia) for sharing their fungal collections. We thank Tyler Remick for his help collecting and curating ascocarps. Andrew Uccello and Chris Burke assisted in the fieldwork with additional help from Karrah Kwasnik, among other volunteers, at Bartlett Experimental Forest. Rebecca Rowe provided sampling supplies and constant encouragement and Mariko Yamasaki granted access to sampling at Bartlett Experimental Forest. Scanning electron micrographs of *E. bartlettii* ascospores were produced at the N.C. Brown Center for Ultrastructure studies using a JEOL JSM-5800LV scanning electron microscope by Austin Frewert. Todd F. Elliott provided photographs of *E. oreoides* and *E. verruculosus*. We thank Terry Henkel, Todd F. Elliott, and an anonymous reviewer for comments which improved the manuscript. Partial funding was provided by the New Hampshire Agricultural Experiment Station. This is Scientific Contribution Number 2684. This work was supported by the USDA National Institute of Food and Agriculture McIntire-Stennis Project (0229197 & 1006881). Additional ascocarp sampling in 2015 was supported by a grant from the North American Truffling Society.
